

Quotes lasting seconds or days

What stays the same. I leave quote duration undecided without weakening acceptance. Every quote has an expiry. Acceptance checks the exact selected quote, its expiry, the request deadline, every market's eligibility and the maker's full reservation of payout - stake. It also checks requester funds. The fill, escrow funding, rival-reservation releases and command receipt commit atomically. Identical retries return the recorded result without moving money again.

What changes. Seconds-long quotes need frequent renewal, latency-aware collection/acceptance windows and prompt expiry processing. Selection only starts after collection closes. Days-long quotes reserve capital for longer, reduce maker capital efficiency and increase stale-price risk. I would revisit maximum duration, capital limits, cancellation/repricing rules and recovery frequency. Today, ordinary quotes can be cancelled only during collection; capacity replacements are firm immediately, and surviving quotes become firm when collection closes. There is no in-place repricing or automatic reselection. Longer timestamps alone do not make that policy safe for days.

What I built to keep the choice cheap. Expiry is an absolute timestamp stored per quote, bounded by the request acceptance deadline and market cutoffs, rather than a fixed lifetime scattered through the code. An injected clock is read under the writer lock. Acceptance and recovery use shared lifecycle checks; expiry and closure use the same reservation-release logic. Allowed durations and surrounding policies can therefore change without rewriting the acceptance transaction. Expiry is enforced even if cleanup is late, but releasing idle reservations still needs caller-driven recovery. Scheduling, monitoring and renewal policy remain operational decisions.
